recent FDA black box warnings
specific to neonates

Conclusions

neonatologists are working at the fast lane of (developmental) life, age or size/weight are the most significant covariates.

in general, drug clearance is low. This – however – does not exclude extensive interinidividual variability within the neonatal population (size log value).

this extensive interindividual variability in drug disposition necessitates the search for covariates within the neonatal population.

there is no such thing as ‘an isolated neonatal liver/kidney’
main route of clearance should not be similar in neonates compared to adults.

pattern recognition matters, and may be used to predict PK for yet unknown drugs.

distribution volume: hydrophylic drugs

Table 1. Dosing chart recommended with specific doses and intervals according to the GA at birth

	VD, l/kg (mean ± 1 SD)	Half-life, h (mean ± 1 SD)	CL, ml/kg/min (mean ± 1 SD)	Dose mg/kg	Interval h
Group 1a (<28 weeks)	0.700±0.151	12.20±3.83	0.73±0.148	20	42
Group 1b (28 to <31 weeks)	0.660±0.120	8.40±1.36	0.87±0.127	20	36
Group 2 (31 to <34 weeks	0.614±0.013	7.71±0.31	0.98±0.025	18.5	30
Group 3 (34 to <37 weeks)	0.573±0.013	6.77±0.32	1.09±0.061	17	24
Group 4 (37–41 weeks)	0.520±0.021	5.55±0.49	1.15±0.036	15.5	24

The dosing chart was based on population-specific pharmacokinetic parameters calculated during the previous studies, using a pharmacokinetic programme assuming a one-compartment model [27, 28]. Assuming the pharmacokinetic results obtained in the previous study [27] in clinical unstable conditions such as asphyxia, prolonged hypoxia or concomitant treatment by indomethacin, we also recommended in the present study increasing the interval by 6 h, whatever the group, in these encountered clinical situations. For definitions, see text. VD = Volume of distribution; CL = clearance of amikacin.
